Calculation of Mw Averages

Precision Detectors

What Do We Mean By ABSOLUTE?

- There are **4 Absolute Methods of Measuring MW**
- 1) Membrane **Osmometry** (Number Average MW)
- 2) **Light Scattering** (Weight Average MW)
- 3) **Sedimentation Equilibrium** (Ultracentrifugation) (z-average MW)
- 4) **Mass spectroscopy**
- **NO** Reference to standards of mass
- **NO** assumptions of molecular model/conformation
- **ALL** parameters measured directly from 1st principles
 - **Refractive indices**
 - **geometries of cell and detector**
 - **wavelength**
 - **concentrations**
 - **detector response**
 - **temperature**
 - **dn/dc**

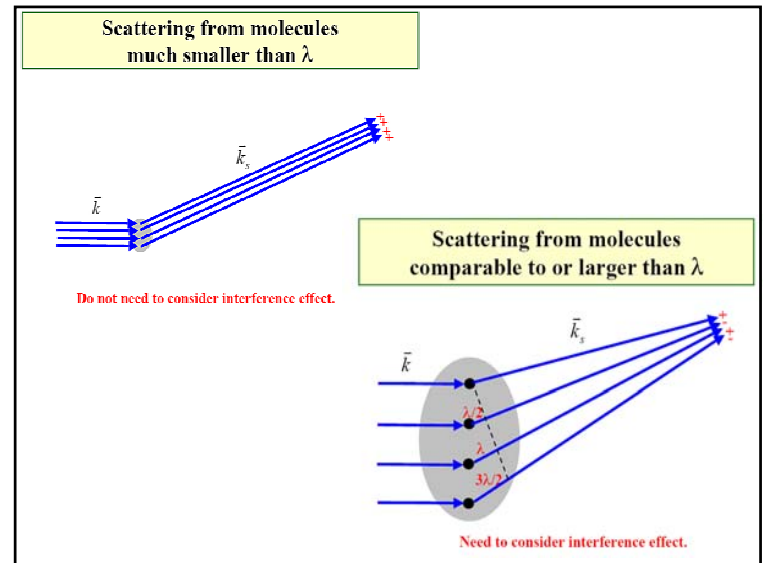

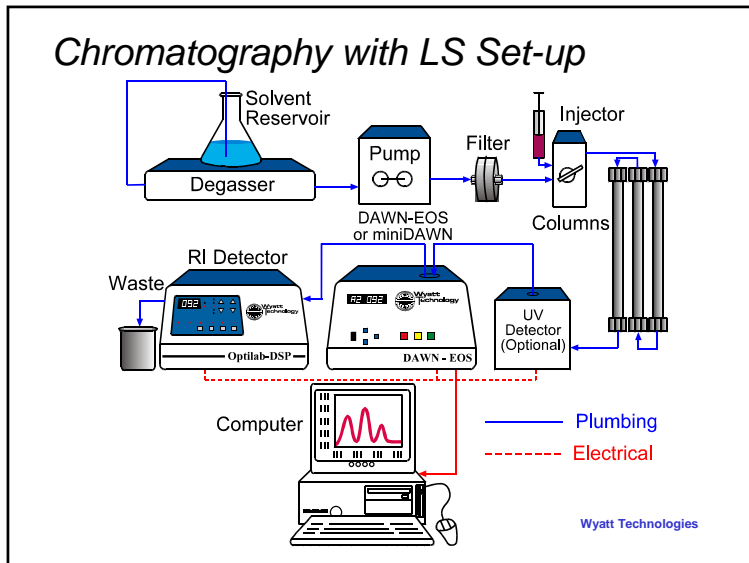

Wyatt Technologies

Abstract

Precision Detectors

Recent advances in genomics and proteomics have produced a proliferation of new proteins requiring characterization. **Mass spectrometry** is ideally suited for identification and **primary structural** purposes but is **not well suited for determining conformational structures in solution**. As these molecules are expressed in cell culture, purified and then formulated, rigorous production processes must be carefully evaluated to minimize impact on the protein structure and its long-term shelf life. **Obtaining a conformational stability profile of protein or antibodies can help weed out bad drug candidates from good ones as environmental factors can change their tertiary and quaternary structure. Environmental factors include pH, ionic strength, temperature, and excipient composition.**

HPLC is used in flow injection mode with a detector array composed of **laser light scattering (static and dynamic modes)** and a concentration source detector (RI or UV). This configuration determines the average molecular weight and average hydrodynamic radius with run times as **short as 1 minute**. Alternatively, a SEC guard column can be used isolate analyte from excipients (eliminating blank runs) with run times under 3 minutes.

EM wave scattered by a ^{small} molecule

molecule size $< \lambda$

Dipole induced in the molecule at the origin

$$\vec{p} = \alpha \vec{E} = \alpha \vec{E}_0 e^{i\omega t} \quad E_0: \text{incident field}$$

Electromagnetic wave emitted by the oscillating dipole

$$E = \frac{4\pi^2 \alpha E_0 \sin \phi}{\lambda^2 r} e^{i(\omega t - \vec{k} \cdot \vec{r})}$$

EM wave scattered by a molecule

Electromagnetic wave emitted by the oscillating dipole

$$E = \frac{4\pi^2 \alpha E_0 \sin \phi}{\lambda^2 r} e^{i(\omega t - \vec{k}_s \cdot \vec{r})}$$

Scattering intensity to the incident intensity

$$\frac{I}{I_0} = \frac{16\pi^4 \alpha^2 \sin^2 \phi}{\lambda^4 r^2} \quad \text{for polarized incident light of intensity } I_0$$

Scattering from molecules much smaller than λ

molecule size $\ll \lambda$

$$\frac{I(\theta)}{I_0} = \frac{2\pi^2 n_0^2}{A \lambda^4 r^2} \left(\frac{dn}{dC} \right)^2 CM (1 + \cos^2 \theta)$$

Light scattering can be used to determine the molecular weight.

Define "Raleigh Ratio" R_θ

$$R_\theta = \frac{I(\theta)}{I_0} \frac{r^2}{(1 + \cos^2 \theta)}$$

$$R_\theta = KCM \quad \text{or} \quad \frac{K^*c}{R(\theta)} = \frac{1}{M}$$

EM wave scattered by a molecule

Scattering intensity to the incident intensity

$$\frac{I}{I_0} = \frac{8\pi^4 \alpha^2 (1 + \cos^2 \theta)}{\lambda^4 r^2} \quad \text{for unpolarized incident light}$$

$$I \propto 1/r^2 ; \quad I \propto 1/\lambda^4 ; \quad I \text{ depends on scattering angle}$$

Basic Light Scattering Principles

- The **amount of light scattered** is directly proportional to the product of the **molar mass** and the **molecular concentration**

$$I_{LS} = C M_w \left(\frac{dn}{dc} \right)^2 P_\theta K_\theta$$

- The **variation of scattered light** with scattering angle is proportional to the **average size** of the scattering molecules.

$$\frac{K^*c}{R(\theta)} = \frac{1}{M} \left[1 + \frac{16\pi^2}{3\lambda^2} \langle r_g^2 \rangle \sin^2(\theta/2) + \dots \right] + 2 A_2 c$$

Static Light Scattering Detection

Determines

- Absolute Molecular Weight
Independent of Column Calibration
- Radius of Gyration (R_g)
> 10 nm to 150 nm

$$I_{LS} = C M_w (dn/dc)^2 P_\theta K_\theta$$

Rayleigh Equation

Diagram labels for the Rayleigh Equation:

- C : Concentration of Solute
- M_w : Molecular Weight
- $(dn/dc)^2$: Specific Refractive Index Increment
- P_θ : Form Factor
- K_θ : Detector Constants

Excess Light Scattering Signal

Precision Detectors

Accuracy of Molecular Masses of Test Proteins Determined by Light Scattering

Protein	Mass From Structure [Da]	Light Scattering* [Da]	Apparent Error [%]
Carbonic anhydrase	29,023	29,800	+2.7
Alcohol dehydrogenase	145,980	149,000	+1.4
β -Amylase	224,340	228,000	+1.6
Apoferritin	476,316	484,400	+1.7
Thyroglobulin	669,000	679,000	+1.5
Ornithine decarboxylase	990,684	978,000	-1.3
Octopus Hemocyanin	3,440,000	3,450,000	+0.3

*DAWN detector model-F, 0.19 was used as dn/dc value for all the proteins
Adapted from "Assembly of the Gigantic Hemoglobin of the Earthworm *Lumbricus terrestris* by A. Riggs *et al.* In *J. Bio. Chem.*, Vol. 271, No. 47, pp 30007-30021, 1996.

Basic Light Scattering Equation

$$\frac{K^*c}{R(\theta)} = \frac{1}{M_w P(\theta)} + 2A_2c$$

Where:

$$K^* = 4\pi^2 (dn/dc)^2 n_0^2 / (N_A \lambda_0^4)$$

n_0 is the refractive index of the solvent.

c is the concentration of the solute molecules (g/ml).

$R(\theta)$ is the fraction of light scattered per unit solid angle, in excess of the light scattered by the solvent, divided by the incident intensity.

N_A is Avogadro's number.

λ_0 is the vacuum wavelength of the incident light.

dn/dc is the refractive index increment, which tells how much the refractive index of the solution varies with solute concentration.

M_w is the weight-average molar mass.

Wyatt Technologies

RI & Light Scattering Combined for M_w

$$R_\theta = C M (dn/dc)^2 P(\theta) K(\theta) \quad \text{Rayleigh Equation}$$

$$RI_{\text{signal}} = K_{RI} (dn/dc) C \quad \text{RI Equation}$$

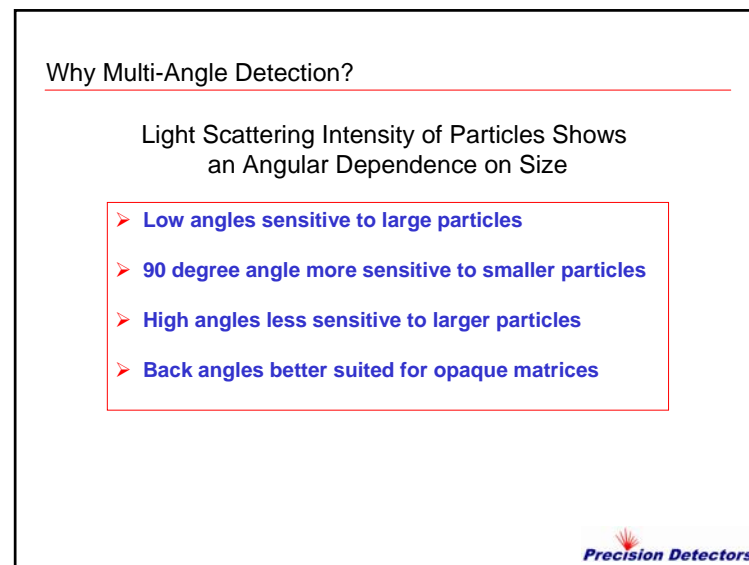

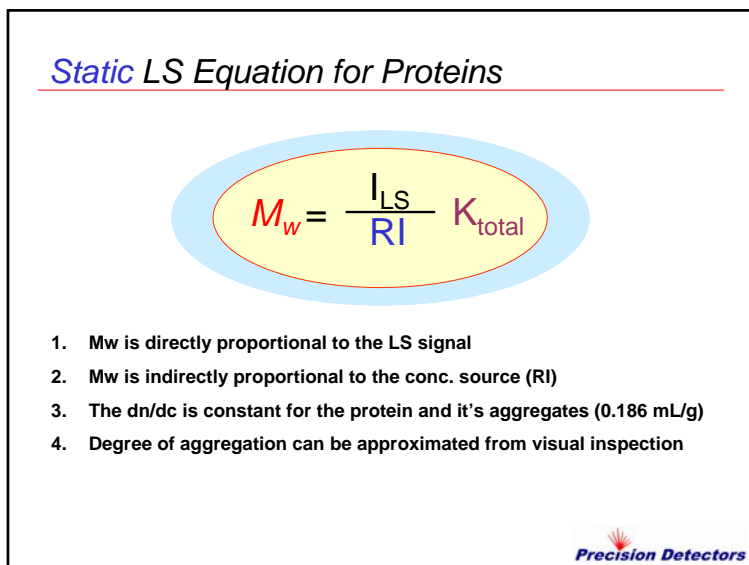

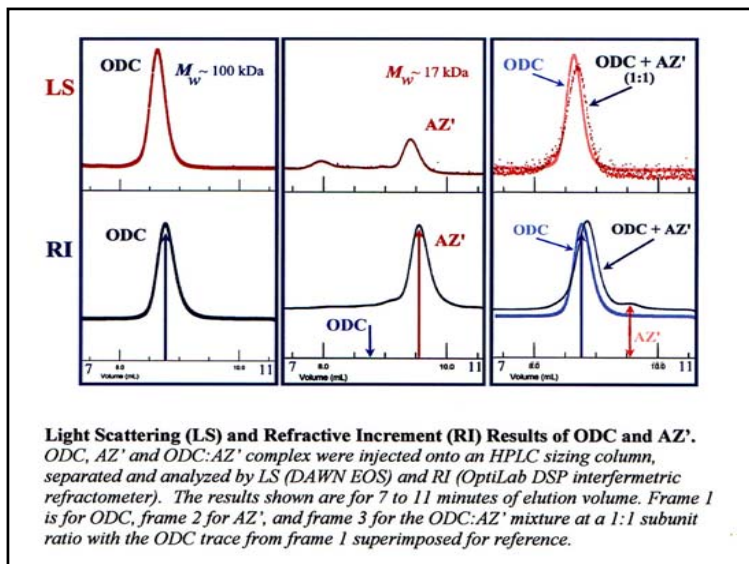

$$\frac{R_\theta}{RI_{\text{signal}}} = \frac{K(\theta) M_w (dn/dc) P(\theta)}{K_{RI}}$$

$$\frac{R_\theta}{RI_{\text{signal}}} \sim M_w$$

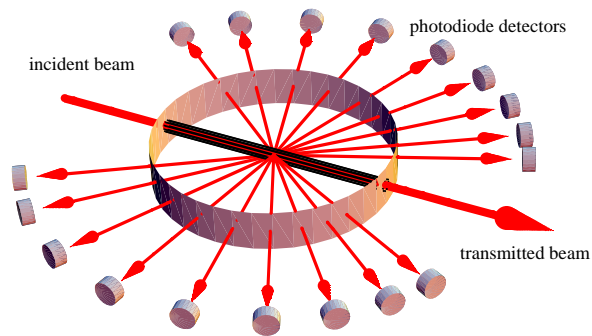

For a truly effective measurement of molecular weight the static light scattering detector must be combined with a well matched refractometer

- The light scattering signal is directly proportional to the M_w .
- The concentration source signal (e.g. RI) is indirectly proportional to the M_w .

Precision Detectors

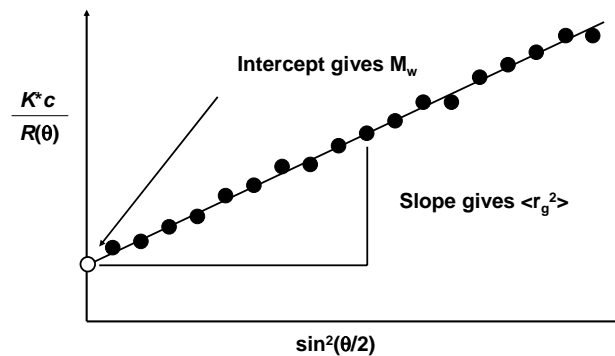

Flow Cell & Detector Geometry

Wyatt Technologies

M_w & $\langle r_g^2 \rangle$ determined by MALS

$$\frac{K^*c}{R(\theta)} = \frac{1}{M} \left[1 + \frac{16\pi^2}{3\lambda^2} \langle r_g^2 \rangle \sin^2(\theta/2) + \dots \right] + 2 A_2 c$$

ALS4000 Optical Platform Features

- 1 Diode laser: 230 mW @ 830 nm (adjustable)
- 2 Flow Cell (30 uL)
- 3 Peltier cooling/heating (0 to 80 degrees C)
- 4 Laser Beam Stop
- 5 DLS Detectors (Up to 4)
- 6 Static LS Detectors (Up to 8)

DLS Detector

Precision Detectors

$$\langle r_g^2 \rangle = \frac{\sum r_i^2 m_i}{M}$$

- $\langle r_g^2 \rangle$ is the mean square radius, relating to the distribution of mass within the molecule, given by

Wyatt Technologies

Why use R_h instead of R_g for Biomolecules?

Precision Detectors

Hydrodynamic Radius Determination

Precision Detectors

From $g_1(\tau)$ the diffusion coefficient (D) for the scattering particles can be determined. From the diffusion coefficient, the hydrodynamic radius can be calculated.

$$D_0 = \kappa T (6\pi \eta_0 R_h)^{-1}$$

Stokes-Einstein Equation

Applicable DLS Size Range

1.5 to 1000 nm Radius

Dynamic Light Scattering Detection

Determines

- Molecular or Particle Size
As Hydrodynamic Radius (R_h)
- Size Range
1 to 1000 nm

$$D_0 = \kappa T (6\pi \eta_0 R_h)^{-1}$$

Stokes-Einstein Equation

Precision Detectors

Conclusions on Static and Dynamic LS

- Measures **Hydrodynamic Radius, Radius of Gyration, Molecular Weight, Particle Size Distribution.**
- Instrument Measures
 - R_h size** from 1.7 nm to 1000 nm.
 - R_g size** from 9 nm to 150 nm.
 - Molecular Weight** 200 to 20,000,000 daltons
- Detects branching, aggregates and calculates Mw.
- DLS**, does not require conc or dn/dc measurement for size.
- Batch Mode for non-flow system accessories.

Precision Detectors

Scattering from molecules much smaller than λ

Do not need to consider interference effect.

Scattering from molecules comparable to or larger than λ

Need to consider interference effect.

X-ray scattering

The major scatterers of x-ray in a molecule are electrons.

$$\frac{I(\theta)}{I_0} = \frac{8\pi^4 \alpha^2 (1 + \cos^2 \theta)}{\lambda^4 r^2} \quad \text{Light scattering by a small molecule}$$

↓

$$\frac{I(\theta)}{I_0} = \left(\frac{e^2}{mc^2} \right)^2 \cdot \frac{(1 + \cos^2 \theta)}{2r^2} \quad \text{X-ray scattering by an electron}$$

Scattering from molecules comparable to or larger than λ

$$P(\theta) = \frac{\langle I(\theta) \rangle}{\langle I(0) \rangle} = \exp\left(-\frac{16\pi^2}{3} \cdot \frac{R_G^2}{\lambda^2} \cdot \sin^2 \frac{\theta}{2} \right)$$

Visible light, $\lambda \sim 400 - 700 \text{ nm}$

For molecules with a few nm, scattering of visible light have a very week angular dependence.

↓

Difficult to determine the size of the molecules by scattering of visible light.

Biomolecules absorbs UV light.

↓

x-ray scattering

X-ray scattering

In a solution of molecules that each has Z electrons, and a molecular weight of M , and concentration of C

$$\frac{I(\theta)}{I_0} = \frac{2\pi^2 n_0^2}{A \lambda^4 r^2} \left(\frac{dn}{dC} \right)^2 CM (1 + \cos^2 \theta) \quad \text{Light scattering}$$

↓

$$\frac{I(\theta)}{I_0} = \frac{1}{2r^2} \left(\frac{e^2}{mc^2} \right)^2 \left(\frac{Z}{M} \right)^2 AMC (1 + \cos^2 \theta) \quad \text{X-ray scattering}$$

Z_0 : number of solvent electrons in the volume of a solute molecule

$$\frac{I(\theta=0)}{I_0} = \frac{1}{r^2} \left(\frac{e^2}{mc^2} \right)^2 \left(\frac{Z}{M} \right)^2 AMC$$

X-ray scattering can be used to determine the molecular weight.

Small angle X-ray scattering (SAXS)

The size of the molecules are always larger than $\lambda \sim 0.1$ nm.

$$P(\theta) = \frac{\langle I(\vec{S}) \rangle}{\langle I(0) \rangle} = \frac{1}{N^2} \sum_{j=1}^N \sum_{i=1}^N \frac{\sin 2\pi S r_{ij}}{2\pi S r_{ij}} \quad S = \frac{2}{\lambda} \sin \frac{\theta}{2}$$

$Sr_{ij} \ll 1$ only at very low angle

At very low angle $SR_G \ll 1$

$$P(\theta) = \frac{\langle I(\theta) \rangle}{\langle I(0) \rangle} = \exp\left(-\frac{4\pi^2 S^2 R_G^2}{3}\right)$$
